

V3 Stablecoin Pool Deployment Plan

Last Updated: April 7, 2026

Status: Contracts deployed, pools not yet created

Executive Summary

KalySwap V3 contracts are deployed to KalyChain mainnet (Chain ID: 3888) as of April 6, 2026. The next step is creating stablecoin liquidity pools. This document outlines what needs to happen, what's already configured, and what requires manual action.

Current State

- **V3 Contracts:** All 8 core contracts deployed and verified
- **V3 Subgraph:** Configured for mainnet, ready to index
- **Stablecoin Tokens:** USDT, USDC, DAI already exist on KalyChain and are pre-configured in all config files
- **Pools:** None created yet

Two Ways to Create V3 Pools

There are two options for getting liquidity into V3 pools. Both are valid and can be used together.

Option A: Create Fresh V3 Pools

Create brand new V3 pools and add fresh liquidity to them. This is the simplest approach — go to the KalySwap app, select V3, pick a token pair and fee tier, set a price range, and deposit tokens.

Option B: Migrate Existing V2 Liquidity to V3

If there is already liquidity in V2 pools (e.g., V2 wKLC/USDT), that liquidity can be **migrated directly to V3** using the built-in migration tool. This is done through the KalySwap web app — no terminal commands needed.

How it works for liquidity providers:

1. Go to the **Pools > Migrate** page on the KalySwap app
2. Select a V2 LP position to migrate
3. Choose the V3 fee tier (e.g., 0.05% for stablecoin pairs)
4. Set a price range for the V3 position
5. Confirm the migration transaction in your wallet

The migration happens in a single transaction: it removes liquidity from the V2 pair and creates a new V3 position with the specified price range. The starting price is automatically set based on the current V2 market price, so there's no manual price calculation needed.

Key points:

- Migration is per-user — each LP migrates their own position when they're ready

- V2 pools continue to work alongside V3 — nothing breaks for users who don't migrate
- V3 offers better capital efficiency, so LPs earn more fees with less capital in the right price range
- The migration contract is already deployed at `0x1935DC82D5847eE21c4ce39515D26894b3CCADD7`

Recommended Approach

For the initial launch, we recommend **combining both options**:

1. **Seed a fresh wKLC/USDT V3 pool** with initial liquidity (Option A) — this is needed first for the price oracle
2. **Encourage existing V2 LPs to migrate** over time using the migration tool (Option B)
3. **Create remaining pools** (wKLC/USDC, USDT/USDC, etc.) either way

Recommended Initial Pools

Pool	Fee Tier	Why
wKLC/USDT	0.05% (500 bps)	Primary price oracle pool — create this first
wKLC/USDC	0.05% (500 bps)	Secondary stable pair
USDT/USDC	0.01% (100 bps)	Stablecoin-to-stablecoin, minimal impermanent loss
wKLC/DAI	0.05% (500 bps)	DAI pair

The wKLC/USDT pool must be created first — the subgraph uses it as the price oracle to derive USD values for all other tokens.

What's Already Configured (No Changes Needed)

Component	Status	Details
Stablecoin addresses in subgraph whitelist	Done	USDT, USDC, DAI in <code>WHITELIST_TOKENS</code>
Stablecoin addresses in <code>STABLE_COINS</code> list	Done	Used for price classification
Frontend token lists	Done	All stablecoins have logos, decimals, addresses
Fee tier constants	Done	0.01%, 0.05%, 0.3%, 1% all defined
Frontend stablecoin price logic	Done	<code>STABLECOIN_ADDRESSES</code> in <code>contracts.ts</code>
Auto pool discovery	Done	Subgraph indexes <code>PoolCreated</code> events automatically

What Requires Manual Action After Pool Creation

1. Update Subgraph Price Oracle (CRITICAL)

File: `v3-subgraph/config/kalychain-mainnet/chain.ts`

After creating the wKLC/USDT pool, get its address from the `PoolCreated` event and update:

```
// Change from:
export const STABLE_TOKEN_POOL = ''

// Change to:
export const STABLE_TOKEN_POOL = '0x<WKLC_USDT_POOL_ADDRESS>'
```

Impact if not done: All USD price calculations return \$0. Pool TVL, volume, and token prices will show as zero across the entire platform.

2. Rebuild & Redeploy V3 Subgraph

```
cd v3-subgraph
npm run build -- --network kalychain --subgraph-type v3
npx graph deploy --node http://127.0.0.1:8020 --ipfs http://127.0.0.1:5001 \
  --version-label v0.0.2 v3-subgraph-kalychain v3-subgraph.yaml
```

3. Set Frontend Environment Variable

```
NEXT_PUBLIC_V3_MAINNET_SUBGRAPH_URL=http://127.0.0.1:8000/subgraphs/name/v3-
-subgraph-kalychain
```

4. (Optional) Configure Farming Incentives

If offering KSWAP rewards on stablecoin pools, update `frontend/src/config/dex/v3-incentives.ts` with incentive parameters (reward token, pool address, start/end times).

Rollout Steps (Ordered)

#	Step	Who	How
1	Create wKLC/USDT V3 pool + add initial liquidity	Team member with tokens	Via KalySwap app (Pools page, select V3, 0.05% fee)
2	Record the new pool's contract address	Dev team	From the transaction receipt or block explorer
3	Update subgraph price oracle config	Dev team	One line change in config file (see below)
4	Rebuild & redeploy V3 subgraph	Dev team	~30 min
5	Verify pool shows on frontend with USD prices	QA / Dev	Check the Pools and Swap pages

#	Step	Who	How
6	Create remaining pools (wKLC/USDC, USDT/USDC, wKLC/DAI)	Team	Via KalySwap app
7	(Optional) Encourage V2 LPs to migrate to V3	Community / Marketing	Users self-serve via Pools > Migrate page
8	(Optional) Set up farming incentives on V3 pools	Dev team	Config file update

Risk / Gotchas

- **Price depends on first pool:** If wKLC/USDT pool has very low liquidity, price oracle will be inaccurate and susceptible to manipulation. Seed with reasonable liquidity.
- **Decimal mismatch:** USDT and USDC are 6 decimals, wKLC and DAI are 18 decimals. Price initialization must account for this when calculating `sqrtPriceX96`.
- **Subgraph reindex:** After updating `STABLE_TOKEN_POOL`, the subgraph needs to reindex from the start block to recalculate historical USD prices. This takes time depending on how many events have been indexed.

Timeline Estimate

Step	Time
Create pools + add liquidity	1-2 hours
Update subgraph config + redeploy	30 min
Subgraph sync (from block 47564956)	1-4 hours (depends on block count)
Frontend verification	30 min
Total	~Half day
